# Unit #3 & 4 Concurrency & Inter-Process Communication

Department of Computer Engineering

**Operating System** 

Sem 4 3140702 5 Credits

# Topics to be covered

- Introduction to IPC
- Methods for IPC
- Process Synchronization
  - Race Conditions,
  - Critical Section,
  - Mutual Exclusion
- Synchronization Methods Disabling Interrupts, Hardware Solution, Strict Alternation and Peterson's Solution
- The Producer Consumer Problem
- Semaphores
- Event Counters, Monitors, Message Passing
- Classical IPC Problems: Reader's & Writer Problem, Dinning Philosopher Problem and Sleeper Barber Problem

### Introduction to IPC

Processes in system can be independent or cooperating.

1. **Independent processes:** cannot affect or be affected by the execution of another process.

2. **Cooperating processes:** can affect or be affected by the execution of another process.

### Introduction to IPC

Inter-process communication (IPC) is a set of methods for the exchange of data among multiple threads in one or more processes.

Processes may be running on one or more computers connected by a network.

■ IPC may also be referred to as **inter-thread communication** and **inter-application communication**.

# Why IPC?

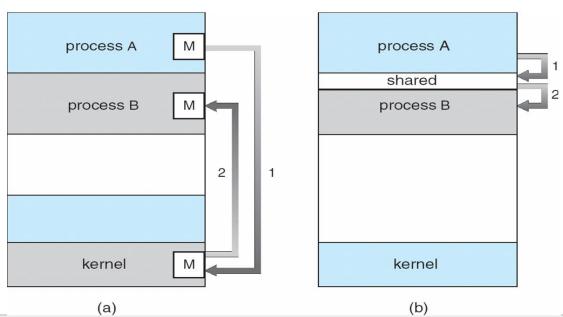

There are several reasons for providing an environment that allows process cooperation:

- Information sharing
- Computational speedup
- Modularity
- Convenience

# Methods of communication

- The communication between these processes can be seen as a method of cooperation between them. Processes can communicate with each other using these two ways:
  - **a. Message Passing** (Process A send the message to Kernel and then Kernel send that message to Process B)
  - **b. Shared Memory** (Process A put the message into Shared Memory and then Process B read that message from Shared Memory)

### Race Condition

 A Race condition is an undesirable situation that occurs when a device or system attempts to perform two or more operations at the same time.

 Operations upon shared states are critical sections that must be mutually exclusive. Failure to do so opens up the possibility of corrupting the shared state.

• Race condition: Situations like this where processes access the same data concurrently and the outcome of execution depends on the particular order in which the access takes place is called race condition.

### **Basic Definitions**

- Situation where two or more processes are reading or writing some shared data and the final result depends on who runs precisely when.
- Mutual Exclusion and Critical Section
- Critical Section: The part of program where the shared resource is accessed is called critical section or critical region.
- Mutual Exclusion: Way of making sure that if one process is using a shared variable or file; the other process will be excluded (stopped) from doing the same thing.

# Critical Section (Critical Region)

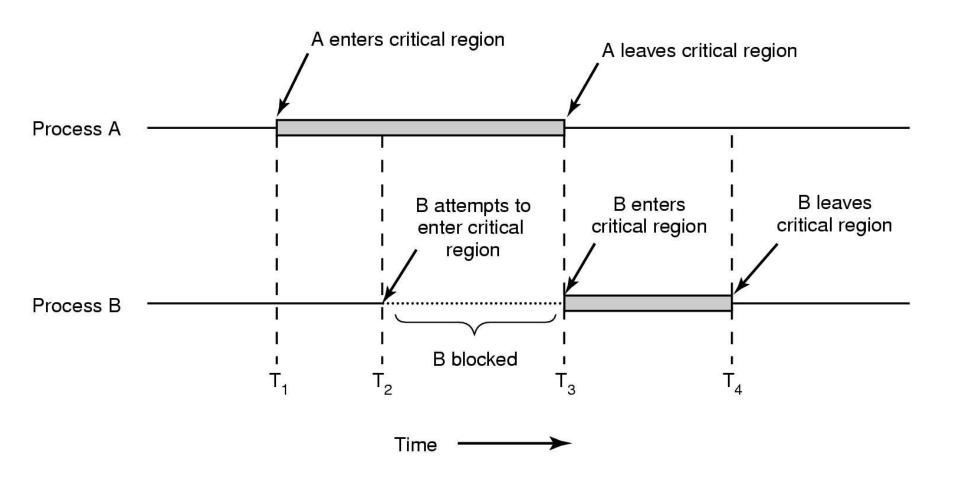

Sometimes a process has to access shared memory or files, or do other critical things that can lead to races. This type of part of program where shared memory is accessed is called the critical region or critical section.

If no two processes are ever in their critical regions at the same time then we could avoid race.

# What we are trying to do??? Marwadi

# Solving Critical-Section Problem Narwadi

Any solution to the CS problem must satisfy following criteria:

#### 1. Mutual Exclusion

- Only one process at an instant of time can enter into critical section.
- Also, critical section must be accessed in mutual exclusion fashion.

### 2. Progress

- Progress says, only consider those processes should compete which actually wants to access or enter into the critical section.
- Also, progress is your mandatory criteria.

#### 3. Bounded Wait

- There should be a maximum bound up to which a process can wait.
- No process should have to wait forever to enter a critical section.

- Synchronization Methods
- 1. Busy Waiting: wastage of time, falling in infinite loop, not doing anything but busy only in knocking.

2. Without Busy Waiting: instead of knocking again and again process will simply goes to rest mode and whenever the process in critical section gets free, will awake another process and notify it to use the critical section.

# **Busy Waiting Solutions for CS Problem**

### A list of proposals to achieve mutual exclusion

- Disabling interrupts
- Lock variables
- 3. Strict alternation
- 4. Flag Variable
- 5. Peterson's solution
- 6. The TSL instruction (Hardware Solution)

# Solution-1. Disabling Interrupts Marway

 Idea: process disables interrupts, enters critical region, enables interrupts when it leaves critical region

#### Problems

- Process might never enable interrupts, crashing system
- Won't work on multi-core (multiprocessor/with two or more CPUs)chips as disabling interrupts only effects only the CPU that executed the disabling instruction.
- the other ones will continue and can access the shared memory.

### A software solution - everyone shares a lock

- When lock is 0, process turns it to 1 and enters in critical region
- When exit critical region, turn lock to 0

#### Problem - Race condition

- suppose that one process reads the lock and sees that it is 0,
   Before it can set the lock to 1, another process is scheduled,
   runs and sets the lock to 1.
- when the first process runs again it will also set the lock to 1 and two processes will be in their critical regions at the same time.

### Lock variable

- While (lock!=0);
- 2. Lock=1;
- 3. Enter in Critical Section
- 4. Lock=0;
- 5. Exit CS

# Solution-3 Strict Alternation

- Integer variable 'turn' keeps track of whose turn is to enter the critical section.
- Initially turn =0
- Process 0 inspects turn, finds it to be 0, and enters in critical section.
- Process 1 also finds it to be 0 and therefore sits in loop continually testing 'turn' to see when it becomes 1.
- countinusoly testing a variable until some value appears is called busy waiting.
- When process 0 exits from critical region it sets turn to 1 and now process 1 can find it to be 1 and enters in to critical region.
- In this way, both the processes get alternate turn to enter critical region.

### For Process PO

```
While (TRUE)
{
while ( turn != 0); /* trap */
Critical_region();
turn =1; /*a process exit CS*/
noncritical_region();
}
```

### For Process P1

```
While (TRUE)
{
  while ( turn != 1); /* trap */
  Critical_region();
  turn =0; /*a process exit CS*/
  noncritical_region();
}
```

# Solution 4. Flag Variable

For Process PO

```
While(True)
Flag[0]=T; /*process is interested
  to enter into CS*/
while ( Flag[1]); /* trap*/
Critical_region();
Flag[0] =F; /*a process exit CS*/
noncritical_region();
```

```
For Process P1
While(True)
Flag[1]=T; /*process is
   interested to enter into CS*/
while (Flag[0]); /* trap*/
Critical_region();
Flag[1] =F; /*a process exit CS*/
noncritical_region();
```

# Solution-5 Peterson's Solution Marw

### For Process PO

```
While(True)
Flag[0]=T; /*process is
   interested to enter into CS*/
Turn = 1;
while (turn==1 && Flag[1]==T);
  /* trap*/
Critical_region();
Flag[0] =F; /*a process exit CS*/
noncritical_region();
```

### For Process P1

```
While(True)
Flag[1]=T; /*process is
   interested to enter into CS*/
Turn = 0;
while ( turn==0 && Flag[0]==T);
  /* trap*/
Critical_region();
Flag[1] =F; /*a process exit CS*/
noncritical_region();
```

```
#define FALSE 0
#define TRUE
#define N
                                         /* number of processes */
                                         /* whose turn is it? */
int turn;
                                         /* all values initially 0 (FALSE) */
int interested[N];
                                         /* process is 0 or 1 */
void enter_region(int process);
     int other;
                                         /* number of the other process */
     other = 1 - process;
                                         /* the opposite of process */
                                         /* show that you are interested */
     interested[process] = TRUE;
                                         /* set flag */
     turn = process;
     while (turn == process && interested[other] == TRUE) /* null statement */;
                                         /* process: who is leaving */
void leave_region(int process)
     interested[process] = FALSE;
                                        /* indicate departure from critical region */
```

# 6. Hardware Solution - TSL (Test & Set Lock) Narwadi

 TSL reads lock into register (RX) and stores NON ZERO VALUE in lock (e.g. process number)

TSL RX,LOCK

 Instruction is atomic: done by freezing access to bus line (memory bus disable)

### Hardware Solution

```
enter_region:
```

TSL REGISTER,LOCK
CMP REGISTER,#0

JNE enter\_region

RET

copy lock to register and set lock to 1

was lock zero?

if it was nonzero, lock was set, so loop

return to caller; critical region entered

leave\_region:

MOVE LOCK,#0

RET

store a 0 in lock

return to caller

### XCHG instruction

### XCHG a, b exchanges a & b

enter\_region:

MOVE REGISTER,#1

XCHG REGISTER,LOCK

CMP REGISTER,#0

JNE enter\_region

RET

put a 1 in the register

swap the contents of the register and lock variable

was lock zero?

if it was non zero, lock was set, so loop

return to caller; critical region entered

leave\_region:

MOVE LOCK,#0

**RET** 

store a 0 in lock

return to caller

# Priority Inversion problem

- Marwadi University
- Priority inversion means the execution of a high priority process/thread is blocked by a lower priority process/thread.
- Consider a computer with two processes, H having high priority and L having low priority. The scheduling rules are such that H runs first then L will run.
- The scheduling rules are such that H is run whenever it is in ready state.
- At a certain moment, with L in its critical region, H becomes ready to run (e.g., an I/O operation completes).
- H now begins busy waiting, but since L is never scheduled while H is running, L never gets the chance to leave its critical region, so H loops forever.
- This situation is sometimes referred to as the priority inversion problem.

# What's wrong with Peterson, TSP ?

- Marwadi On iversity
- When a process wants to enter its critical region, it checks to see if the entry is allowed.
- If it is not, the process just sits in a tight loop waiting until it is allowed to enter.

#### Limitations:

- i. Busy Waiting: this approach waste CPU time
- ii. Priority Inversion Problem: a low-priority process blocks a higher-priority one

# Sleep and Wake up

- To avoid busy waiting we have IPC primitives( pair of sleep and wakeup)
- Solution : Replace busy waiting by blocking calls
  - **Sleep** (blocks process): it is a system call that causes the caller to block, that is, be suspended until another process wakes it up.

 Wakeup (unblocks process): The wakeup call has one parameter, the process to be awakened.

# The Producer-Consumer Problem Marwadi

- It is also known as Bounded Buffer Problem in (multiprocess synchronization problem).
- Consider two processes Producer and Consumer, who share common, fixed size buffer.
- Producer puts information into the buffer
- Consumer consume this information from buffer.
- Trouble arises when the producer wants to put a new item in the buffer, but it is already full.
- And consumer wants to remove a item from buffer,
   but it is already empty.

# The Producer-Consumer Problem Marwadi

### Consumer

```
Void consumer()
int item;
While(True)
   while(count==0); /*buffer
   empty*/
    item= buffer(out);
    out=(out+1)mod n;
    count = count - 1;
    Consume_item(item)
```

### **Producer**

```
int count = 0;
void producer()
    While(True)
    Produce_item(item);
    while(count==n); /*buffer full*/
    Buffer[in]=item;
    in=(in+1) mod n;
    count = count+1;
```

# Solution - Producer-Consumer Problem Marwadi

### Solution for producer:

- Producer either go to sleep or discard data if the buffer is full.
- Once the consumer removes an item from the buffer, it notifies (wakeups) the producer to put the data into buffer.

#### Solution for consumer:

- Consumer can go to sleep if the buffer is empty.
- Once the producer puts data into buffer, it notifies (wakeups)
   the consumer to remove (use) data from buffer.

### Producer Consumer problem using Sleep & Wakeup

```
#define N 4
int count=0;
                                             count
void producer (void)
    int item;
                                             item
                                                    Item 1
    while (true) {
      item=produce item();
                                        Producer
                                                    Buffer
                                                             Consumer
      if (count==N) sleep();
      insert item(item);
                                               2
      count=count+1;
      if(count==1)
                                               4
wakeup(consumer);
```

### Producer Consumer problem using Sleep & Wakeup

```
void consumer (void)
    int item;
                                            count
    while (true)
                                            item
    if (count==0) sleep();
    item=remove_item();
                                        Producer
                                                   Buffer
                                                            Consumer
                                                   Item 1
    count=count-1;
                                               2
    if(count==N-1)
        wakeup(producer);
                                               4
    consume item(item);
```

## The problem with sleep and wake-up calls

- Empty buffer, count==0
- Consumer gets replaced by producer before it goes to sleep
- Produces something, count++, sends wakeup to consumer
- Consumer not asleep, ignores wakeup, thinks count= = 0, goes to sleep
- Producer fills buffer, goes to sleep
- P and C sleep forever
- So, the problem is lost wake-up calls

 A semaphore is a special integer variable that apart from initialization, is accessed only through two standard operations i.e. wait() and signal().

```
Wait() operation

wait(s)
{
    while(s<=0);
    s = s - 1
}</pre>
```

```
Signal() operation
signal(s)
{
    s = s + 1
}
```

# Wait() & Signal() Operation Mary

A simple way to understand wait() and signal() operations are:

wait(): Decrements the value of semaphore variable by 1. If the value becomes negative or 0, the process executing wait() is blocked (like sleep), i.e., added to the semaphore's queue.

■ **signal():** Increments the value of semaphore variable by 1. After the increment, if the pre-increment value was negative (meaning there are processes waiting for a resource), it transfers a blocked process from the semaphore's waiting queue to the ready queue. (like Wake up)

- Semaphore is used for –
- 1. For solving CS problem (Initial Value = 1)
- 2. For deciding the order of execution among processes
- 3. For managing resources

P1, P2, P3 (order of execution that we want is – P2, P1, P3)

We are going to use two semaphore i.e. S1 = 0, S2 = 0

wait(S1)		wait(S2)
P1	P2	Р3
signal(S2)	signal(S1)	

### Types of Semaphores

- There are two types of semaphores as follows:
- 1. Binary Semaphore
- 2. Counting Semaphore

- Semaphores which are restricted to the values 0 and 1 (or locked/unlocked, unavailable/available, up/down) are called binary semaphores (same functionality that mutexes have).
- Semaphores which allow an arbitrary resource count are called counting semaphores(can have possible values more than two)

## Producer Consumer with Semaphores Marwadi

```
Semaphore S = 1 //Take care of critical section
Semaphore E = n //Empty Slots /*n is the size of buffer*/
Semaphore F = 0 //Full Slots
void producer()
while(T){
  produce();
   wait(E) //check empty slots
  wait(S)
                  /*Critical
                        Section*/
  insert_item();
  signal(S)
   signal(F) //incr one in buffer
```

```
void consumer
while(T) {
   wait(F) //check buffer is full
                      /*Critical
 wait(S)
                           Section*/
 remove_item();
 signal(S)
   signal(E) //incr one in buffer
   use();
```

#### Classical IPC Problems

- Readers and Writers Problem
- Dinning Philosopher Problem
- Sleeping Barber Problem

### Reader's Writer's Problem

- Multiple readers can concurrently read from the data base.
- But when updating the DB, there can only be one writer (i.e., no other writers and no readers either)

Case	Process 1	Process 2	Allowed / Not Allowed
Case 1	Writing	Writing	Not Allowed
Case 2	Reading	Writing	Not Allowed
Case 3	Writing	Reading	Not Allowed
Case 4	Reading	Reading	Allowed

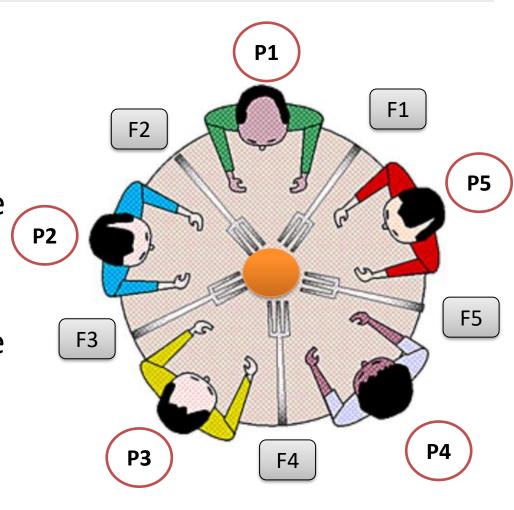

#### Readers-Writers

```
Semaphore wrt = 1 // for writer
Semaphore mutex = 1
                            // for reader
                             /*readcount is a shared variable,
Int readcount = 0
                             which contains the count of readers in
                             the CS*/
       For writer
         wait(wrt)
         write operation;
         signal(wrt)
```

```
For reader
  wait(mutex)
  readcount ++;
  if(readcount==1) /*Actually, here we are checking first reader
                      or not?*/
  wait(wrt)
                    // no writer can enter in CS
  signal(mutex)
  read operation; wait(mutex)
  readcount--;
  if(readcount==0) //Last reader
  signal(wrt) //Now writer can enter in CS
  signal(mutex)
```

# Dinning Philosopher Problem Marwadi

- Philosophers eat and think.
- 1. To eat, they must first acquire a left fork and then a right fork (or vice versa).
- 2. Then they eat.
- Then they put down the forks.
- Then they think.
- Go to 1.

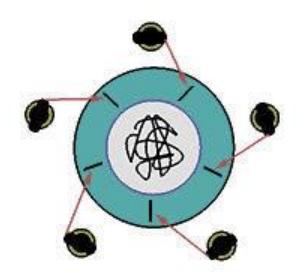

#### What is a Problem?

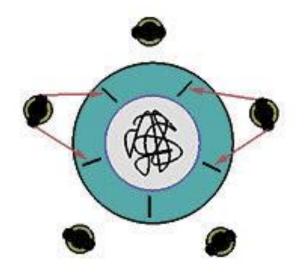

- The dining philosopher's problem is the classical problem of synchronization which says that Five philosophers are sitting around a circular table
- Their job is to think and eat alternatively.
- A bowl of noodles is placed at the center of the table along with five chopsticks for each of the philosophers.
- To eat a philosopher needs both their right and a left chopstick. A philosopher can only eat if both immediate left and right chopsticks of the philosopher is available.
- In case if both immediate left and right chopsticks of the philosopher are not available then the philosopher puts down their (either left or right) chopstick and starts thinking again.

#### Problems:

#### 1. Deadlock

#### 2. Starvation

## Dinning Philosopher Problem

```
Void philosopher()
                                                                 F1
                                                  F2
  while(T)
       think();
                                                                     F5
       take_fork(i);
                               //Left fork
       take fork((i+1)%n); //Right fork
                                                  P3
                                                           F4
       eat();
       put_fork(i);
                               //Left fork
       put_fork((i+1)%n); //Right fork
```

### Solution (Not correct)

Solution of Dining Philosopher problem using Semaphore

```
Void philosopher()
  while(T) {
       think();
       take_fork(Si);
                              //Left fork
       take fork((Si+1)%n); //Right fork
       eat();
                              //Left fork
       put_fork(Si);
       put_fork((Si+1)%n); //Right fork
```

**S[i] five semaphores** (i.e. equal to number of forks) **S1, S2, S3, S4, S5** 

P1 →	S1	S2
P2 <b>→</b>	S2	S3
P3 <b>→</b>	S3	<b>S4</b>
P4 →	S4	<b>S</b> 5
P5 <b>→</b>	S5	S1

#### Solution

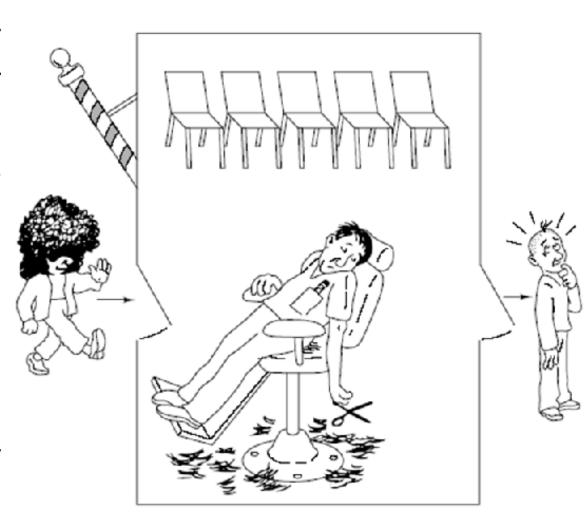

P1 →	S1	S2
P2 →	S2	S3
P3 <b>→</b>	S3	S4
P4 →	S4	S5
P5 <b>→</b>	S1	S5

```
/* number of philosophers */
#define N
#define LEFT
                      (i+N-1)%N /* number of i's left neighbor */
                                    /* number of i's right neighbor */
                      (i+1)%N
#define RIGHT
                                    /* philosopher is thinking */
#define THINKING
#define HUNGRY
                      1
                                    /* philosopher is trying to get forks */
#define EATING
                                    /* philosopher is eating */
typedef int semaphore;
                                    /* semaphores are a special kind of int */
                                    /* array to keep track of everyone's state */
int state[N];
semaphore mutex = 1:
                                    /* mutual exclusion for critical regions */
                                    /* one semaphore per philosopher */
semaphore s[N];
void philosopher(int i)
                                    /* i: philosopher number, from 0 to N=1 */
    while (TRUE) {
                                    /* repeat forever */
        think( );
                                    /* philosopher is thinking */
                                    /* acquire two forks or block */
         take_forks(i);
                                    /* yum-yum, spaghetti */
         eat();
                                    /* put both forks back on table */
        put_forks(i);
}
void take_forks(int i)

```

### Sleeping Barber Problem

- One barber, one barber chair, and N seats for waiting.
- No customers so barber sleeps.
- Customer comes in & wakes up barber.
- More customers come in.
  - If there is an empty seat, they take a seat.
  - Otherwise, they leave.

### Sleeping Barber Problem

```
Semaphore customer = 0
                            // num of customers waiting for haircut
Semaphore barber = 0
                             // barber waiting for customers(sleeping)
                        // for Mutual exclusion among chairs available
Mutex = 1
int NumofEmptyChairs = N;
                                /*total num of seats available at
                                barber shop*/
For Barber {
  while(T) {
       wait(customer); /* waits for a customer (sleeps). */
       wait(mutex); /* mutex to protect the number of available
                              seats.*/
       NumofEmptyChairs++; /* a chair gets free.*/
       signal(barber); /* bring customer for haircut.*/
       signal(mutex); /* barber is cutting hair.*/
```

```
For Customer
  while(T) {
  wait(mutex);
  if(NumofEmptyChairs>0)
       NumofEmptyChairs--; /* sitting down.*/
       signal(customer); /* notify the barber. */
       signal(mutex); /* release the lock */
      wait(barber); /* wait in the waiting room if barber is busy. */
  else
      signal(mutex); /* release the lock customer leaves */
```

### Message Passing

 Semaphores, monitor and event counters are all designed to function within a single system (that is, a system with a single primary memory).

■ They do not support synchronization of processes running on separate machines connected to a network (Distributed System).

 Messages, which can be sent across the network, can be used to provide synchronization.

 So message passing is strategy for inter process communication in distributed environment.

### Typical Message-Passing Function

source and destination addresses must identify the machine and the process being addressed. message is a generic data item to be delivered.

#### √ send (destination, &message);

The calling process sends message to destination without blocking.

#### √ receive (source, &message);

The calling process receives the next sequential message from source, blocking until it is available.

### Producer-Consumer using Message Passing Marwadi

In this solution, each message has two components:

- an empty/full flag, and a data component being passed from the producer to the consumer.
- Initially, the consumer sends N messages marked as "empty" to the producer.
- The producer receives an empty message, blocking until one is available, fills it, and sends it to the consumer.
- The consumer receives a filled message, blocking if necessary, processes the data it contains, and returns the empty to the producer.

```
void producer()
      int item;
                                 // message buffer
      message m;
      while (TRUE)
      item = produce_item();
                                 // generate something to put in
                                  buffer
      receive(consumer, &m);
                                 // wait for an empty to arrive
      build_message (&m, item); // construct a message to send
      send(consumer, &m);
                                 // send item to consumer
```

```
void consumer()
       int item, i;
       message m;
       for (i = 0; i < N; i++) send(producer, &m); //send N empty
                                               messages to producer
       while (TRUE)
              receive(producer, &m); // get message containing item
              item = extract_item(&m); //extract item from message
              send(producer, &m); // send back empty reply
              consume_item(tem); // do something with the item
```

#### Mutex

- When semaphore ability is not needed a simplified version of the semaphore, called a mutex is used.
- Mutexes are good only for managing mutual exclusion to some shared resource.
- A mutex is a variable that can be in one of the two states (only one bit is required to represent it) with 0 meaning unlocked and 1 meaning locked:
  - Unlocked
  - Locked
- Two procedures are used for Mutex:
  - Mutex\_Lock //to enter into CS
  - Mutex\_Unlock //to exit from CS

- Tony Hoare (in 1974) and Per Brinch Hansen (in 1975) proposed a new synchronization structure called a monitor.
- Monitors are features to be included in high level programming languages.
- Processes may call the procedures in a monitor whenever they want to, but they cannot directly access the monitor's internal data structures from procedures declared outside the monitor.

• Monitors have an important property that makes them useful for achieving mutual exclusion:

Only one process can be active in a monitor at any instant.

- When a process calls a monitor procedure, the first few instructions of the procedure will check to see, if any other process is currently active within the monitor.
- If so, the calling process will be suspended until the other process has left the monitor.
- If no other process is using the monitor, the calling process may enter.

 The solution proposes condition variables, along with two operations on them wait and signal.

- When a monitor procedure discovers that it cannot continue (e.g., the producer finds the buffer full), it does a wait on some condition variable, say, full.
- This action causes the calling process to block. It also allows another process that had been previously prohibited from entering the monitor to enter now.

- This other process, for example, the consumer, can wake up its sleeping partner by doing a signal on the condition variable that its partner is waiting on.
- To avoid having two active processes in the monitor at the same time a signal statement may appear only as the final statement in a monitor procedure.

If a signal is done on a condition variable on which several processes are waiting, only one of them determined by the system scheduler, is revived(restore).

### **Monitor Syntax**

```
// Name of monitor
monitor Demo
  Variables;
  condition variables;
  procedure p1();
  end;
  procedure p2();
  end;
end monitor;
```

### Producer Consumer Problem using Monitors iversity

```
monitor ProducerConsumer
condition full , empty ;
integer count;
procedure insert (item : integer );
begin
       if count = N then wait (full );
       insert item (item );
       count := count + 1:
       if count = 1 then signal (empty)
       end;
```

```
function remove (item : integer);
begin
       if count = 0 then wait (empty);
       remove = remove_item ;
       count := count - 1;
       if count = N - 1 then signal (full )
end;
count := 0;
end monitor;
```

### Producer Consumer Problem using Monitors iversity

```
procedure producer;
begin
while true
do
begin
item = produce item;
ProducerConsumer.insert(item)
end
end;
```

```
procedure consumer;
begin
while true
do
begin
item = ProducerConsumer
      .remove;
consume item (item)
end
end;
```

#### **Event Counters**

An event counter is another data structure that can be used for process synchronization. Like a semaphore, it has an integer count and a set of waiting process identifications.

Unlike semaphores, the count variable only increases. It is similar to the "next customer number" used in systems where each customer takes a sequentially numbered ticket and waits for that number to be called.

Read(E): return the count associated with event counter
 E.

 Advance(E): atomically increment the count associated with event counter E.

Await(E, v): if E.count <= v, then continue.</p>

Otherwise, block until E.count > v.

### Producer-Consumer with Event Counters Marwadi

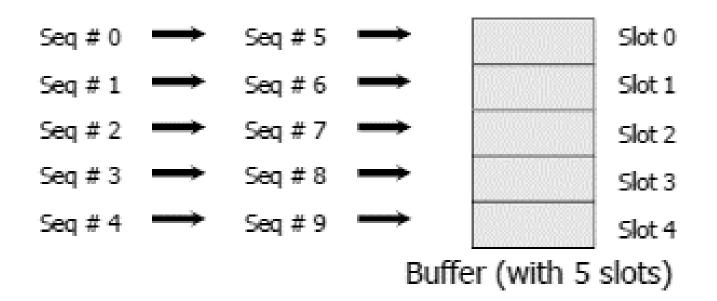

Two event counters are used, in and out, each of which has an initial count of zero.

Each process includes a private sequence variable (v) which indicates the sequence number of the last item it has produced or will consume. Items are sequentially produced and consumed.

Each item has a unique location in the buffer (based on its sequence number), so mutually exclusive access to the buffer is not required.

### Mapping Sequence Numbers to Buffer Locations in the resity

Note that items with sequence numbers 0 and 5 cannot both be in the buffer at the same time, as this would imply that there are six items in the buffer.

### **Pipes**

- Pipe is a communication medium between two or more related or interrelated processes usually between parent and child process.
- Communication is achieved by one process write into the pipe and other process reads from the pipe.
- It performs one-way communication only means we can use a pipe such that one process write into the pipe, and other process reads from the pipe.
- It opens a pipe, which is an area of main memory that is treated as a "virtual file".
- It is bounded buffer means we can send only limited data through pipe.
  Pipe

### **Pipes**

- Accessed by two associated file descriptors:
  - fd[0] for reading from pipe
  - fd[1] for writing into the pipe
